LANGUAGE: English
ENTRY DATE: Entered STN: 20041108
Last Updated on STN: 20041108

AB Background: The objective of this research was to investigate the reproducibility of cross-species **microarray** hybridization. Comparisons between same- and cross-species hybridizations were also made. Nine hybridizations between a single **pig** skeletal **muscle** RNA sample and three human **cDNA** nylon **microarrays** were completed. Three replicate hybridizations of two different amounts of **pig** RNA, and of human skeletal **muscle** RNA were completed on three additional **microarrays**. Results: Reproducibility of **microarray** hybridizations of **pig cDNA** to human **microarrays** was high, as determined by Spearman and Pearson correlation coefficients and a Kappa statistic. Variability among replicate hybridizations was similar for human and **pig** data, indicating the reproducibility of results were not compromised in cross-species hybridized. The concordance between data generated from hybridizations using **pig** and human skeletal **muscle** RNA was high, further supporting the use of human **microarrays** for the analysis of gene expression in the **pig**. No systematic effect of stripping and reusing nylon **microarrays** was found, and variability across **microarrays** was minimal. Conclusion: The majority of genes generated highly reproducible data in cross-species **microarray** hybridizations, although approximately 6% were identified as highly variable. Experimental designs that include at least three replicate hybridizations for each experimental treatment will enable the variability of individual genes to be considered appropriately. The use of cross-species **microarray** analysis looks promising. However, additional validation is needed to determine the specificity of cross-species hybridizations, and the validity of results.

AB Recent developments in **microarray** technologies permit scientists to analyze expression of thousands of genes simultaneously in diverse biological systems. In an effort to provide integrated resources for application of **microarray** technologies to studies of skeletal **muscle** growth and development in **swine**, we have constructed a normalized **cDNA** library from **porcine** skeletal **muscle**. The effectiveness of normalization was evaluated by DNA sequencing of clones randomly picked from the library before and after normalization, and also by Southern blot hybridization using probes representing abundant transcripts. Our data suggests that the normalization procedure successfully reduced the highly abundant **cDNA** species in the normalized library. To date, a total of 782 EST (expressed sequence tag) sequences have been generated from this normalized library (687 ESTs) and the original library (95 ESTs). The sequence information of these ESTs plus their BLAST results has been made available through a web accessible database (http://nbfgc.msu.edu). Cluster analysis of the data indicates that a total of 742 unique sequences are present in this collection. BLASTN search of the 742 EST sequences against the public database (dbEST) revealed that 139 had no significant matches (E-value > 10(-15)) to **porcine** ESTs already entered in the database, suggesting the possibility of their specific expression in **porcine** skeletal **muscle**. Generation of

non-redundant ESTs from this library will allow us to construct **cDNA microarrays** for identification of gene expression changes that regulate **muscle** growth and affect meat quality in **swine**.

AB Purpose: **Microarray** analysis was used to determine if **porcine cDNA** would hybridize cleanly to human **cDNA arrays**. Gene expression from ocular tissues was measured and compared to help elucidate their functions. It was sought to determine if unique gene upregulation in different ocular tissues occurs, and if so what genes are involved. Methods: Total RNA was extracted from **porcine** iris, cilliary body, retina, and optic nerve tissues. Labeled **cDNA** was generated using the Perkin Elmer TSA kit. Samples were hybridized to human **cDNA microarrays** containing 5700 PCR products spotted in duplicate. Amplicons making up the **arrays** are genes or ESTs, and are amplified from ResGen human library clones. Labeled cilliary body, optic nerve, and retina **cDNA** were each hybridized separately with labeled iris **cDNA** on two double spotted **arrays**. Results: It was found that there are genes which are upregulated uniquely in each of the ocular tissues studied. Cilliary body uniquely upregulated genes included lysyl oxidase - like1 (LOXL1), ATP1 B3 ATPase, Na+/K+ transporting, beta 3 polypeptide, FMOD Fibromodulin, GPNMB Glycoprotein (transmembrane) nmb, and OAT Ornithine aminotrasferase (gyrate atrophy). In Iris Beta A1 Crystallin (CRYBA1), and Actin gamma 2 smooth **muscle** enteric (ACTG2) were uniquely upregulated. Myelin Basic Protein (MBP), Proteolipid protein 1 (PLP1), Myelin - associated oligodendrocyte basic protein (MOBP), and S100 calcium - binding protein beta (SB100) were unique to optic nerve. In Retinal tissue CKMT2 creatine kinase mitochondrial 2 (sarcomeric), UNC119 (c. elegans) homolog, and ATPB2 ATPase Na+/K+ transporting beta 2 polypeptide were found to be uniquely upregulated. Conclusion: Upregulated genes in **porcine** ocular tissues could be determined by **microarray** analysis with SMChum5700 human **cDNA arrays** from the Spotted **Microarray** Core at Oregon Health and Science University. Genes that are upregulated specific to tissue type are able to be determined using these **arrays**.
